

Since Algorithm 1 $\in GI$ and solves the ... problem, it is in GI

Algorithm 1: *Fitting algorithm for FO[S]*

Input: Set of labeled examples for FO[S]: $E \subseteq \mathcal{X}_{\text{FO[S]}} \times \{+, -\}$

Output: A concept $\varphi \in C_{\text{FO[S]}}$ if fitting concepts for E exist, else “NONE EXISTS”

```

1  |  $\varphi \leftarrow \perp$ 
2  | foreach  $(A, +) \in E$ 
3  |    $\varphi \leftarrow \varphi \vee \varphi_A$ ; where  $\varphi_A$  is the canonical example for  $A$  constructed as in (a)
4  |   foreach  $(B, -) \in E$  // test if  $\varphi$  fits the negative examples
5  |     if  $A \overset{\text{iso}}{\cong} B$ 
6  |     | return “NONE EXISTS”
7  | return  $\text{TRUE}$ 

```
